

# ATAC-seq

Thomas Juettemann, EMBL-EBI

Lars Grønvold, NMBU

Gareth Gillard, NMBU

aqua\_faang\_course@ebi.ac.uk

May 10-12, 2021

## 1 Introduction

The aim of this section is to investigate open chromatin regions in different tissues. There are 4 sample replicates from brain (B), 4 from liver (L) and 4 from spleen (SP). We are starting out with the BAM alignment files, which have been downloaded into the folder **train-aquafaang-bioinf/data** in the training home directory. The BAM files are sorted by mapping position. Duplicates/multi-mapped reads and reads mapping to mitochondrial chromosome or unplaced scaffolds have been removed from all files. For simplicity, we are only processing replicate 1 from the brain samples (B-1). For the other sample replicates, all files have been made available in the respective folder.

If you are stuck or simply want to move on to the next section, each target directory contains a folder **solution**, which, quite obviously, contains the expected output:

- \$HOME/train-aquafaang-bioinf/atac-seq/ref\_genome/solution
- \$HOME/train-aquafaang-bioinf/atac-seq/results/genrich/solution
- \$HOME/train-aquafaang-bioinf/atac-seq/results/mkarv/solution
- \$HOME/train-aquafaang-bioinf/atac-seq/results/ataqv/solution
- \$HOME/train-aquafaang-bioinf/atac-seq/data/solution

All processing is done using Docker with containerised applications. When testing the total runtime of all commands was around 25 minutes. This does not include loading files in IGV.

Lastly, a few steps involve manipulating files using command line utilities, namely *wget*, *grep* and *cut*. If you are new to using the terminal and command line, copy the instructions from the solution.

## Container

Tool	Container	Documentation
samtools	<a href="#">juettemann/samtools:latest</a>	<a href="http://www.htslib.org/doc/sam.html">http://www.htslib.org/doc/sam.html</a>
Genrich	<a href="#">juettemann/genrich:0.6</a>	<a href="https://github.com/jsh58/Genrich">https://github.com/jsh58/Genrich</a>
bedgraphtobigwig	<a href="#">quay.io/biocontainers/ucsc-bedgraphtobigwig:377-h0b8a92_2-</a>	<a href="https://genome.ucsc.edu/goldenPath/help/bigWig.html#Ex3">https://genome.ucsc.edu/goldenPath/help/bigWig.html#Ex3</a>
ataqv	<a href="#">quay.io/biocontainers/ataqv:1.2.1-py27h97b49fa_1</a>	<a href="https://github.com/juettemann/ataqv/tree/patch-1">https://github.com/juettemann/ataqv/tree/patch-1</a>

Table 1: Container used in this tutorial

## File formats

Extension	Description	Documentation
sam	Sequence Alignment/Map file format	<a href="http://www.htslib.org/doc/sam.html">http://www.htslib.org/doc/sam.html</a>
bam	Binary Format of Sequence Alignment/Mapping (SAM)	<a href="https://genome.ucsc.edu/ENCODE/fileFormats.html#BAM">https://genome.ucsc.edu/ENCODE/fileFormats.html#BAM</a>
bigWig	Genome Browser Signal (Wiggle) Files in Indexed Binary Format	<a href="https://genome.ucsc.edu/ENCODE/fileFormats.html#bigWig">https://genome.ucsc.edu/ENCODE/fileFormats.html#bigWig</a>
narrowPeak	ENCODE narrowPeak: Narrow (or Point-Source) Peaks format	<a href="https://genome.ucsc.edu/FAQ/FAQformat.html#format12">https://genome.ucsc.edu/FAQ/FAQformat.html#format12</a>
faidx	An index enabling random access to FASTA and FASTQ files	<a href="http://www.htslib.org/doc/faidx.html">http://www.htslib.org/doc/faidx.html</a>

Table 2: File formats used in this tutorial

## 2 Variables

In order to make commands shorter and allow less chance for errors, we are setting a few environment variables. These have already been set in the `.bashrc`.

## 3 Reference Genome

Like other \*-seq experiments, also ATAC-seq relies on a reference genome. We will be using the *International Cooperation to Sequence the Atlantic Salmon Genome version 2 (IC-SASG\_v2)* genome from 2015 for this course. General information about the assembly can

## ATAC-seq tutorial

be found at Ensembl ([https://www.ensembl.org/Salmo\\_salar/Info/Index](https://www.ensembl.org/Salmo_salar/Info/Index)). On that page you also find links to FASTA files with the DNA sequence (reference genome) and gtf files with the Ensembl gene annotation.

### 3.1 Download

Your first task is to find, download and unzip the atlantic salmon reference sequence

#### Task

1. Open a terminal
2. Change directory to `$dir_atac/ref_genome`.
3. On the Ensembl assembly page, find the DNA sequence in FASTA format.
4. Click on the link (you will be redirected to a FTP directory).
5. Locate **toplevel** FASTA file (.fa).
6. Right-click on it and choose *Copy Link Location*
7. In the terminal, download the file using *wget*
8. Unzip (*gunzip*)
9. Runtime: Download 70s, Unzip 20s

#### Solution

### 3.2 Create FASTA index

Using an fai index file in conjunction with a FASTA file containing reference sequences enables efficient access to arbitrary regions within those reference sequences. The index file typically has the same filename as the corresponding FASTA, with .fai appended. An fai index file is a text file consisting of lines each with five TAB-delimited columns for a FASTA file:

1. NAME Name of this reference sequence
2. LENGTH Total length of this reference sequence, in bases
3. OFFSET Offset in the FASTA/FASTQ file of this sequence's first base
4. LINEBASES The number of bases on each line
5. LINEWIDTH The number of bytes in each line, including the newline

## ATAC-seq tutorial

Using a samtools container, index the fasta file (*Salmo\_salar.ICSASG\_v2.dna.toplevel.fa*). This resulting index file's name should be *Salmo\_salar.ICSASG\_v2.dna.toplevel.fa.fai*

### Task

1. Pull the container **juettemann/samtools:latest**
2. Using **faidx** from the container, index *Salmo\_salar.ICSASG\_v2.dna.toplevel.fa* (Documentation: <http://www.htslib.org/doc/samtools-faidx.html>)
3. Runtime: 10s

### Solution

## 3.3 Create list of chromosomes

At a later stage in the tutorial, we need a list of all autosomal chromosomes. Using the command line utilities `grep` and `cut`, create a file containing only the chromosome names. As mentioned above in the `faidx` description, the name of the reference sequence is the first column in the FASTA index file, and chromosomes start with *ssa*.

### Task

1. Using **grep** and **cut**, extract all chromosome names
2. Store the names in in the `$dir_atac/ref_genome` folder in a file named **Ssal\_chrm.txt**
3. Runtime: Instant

### Solution

## 3.4 Create table with chromosome sizes

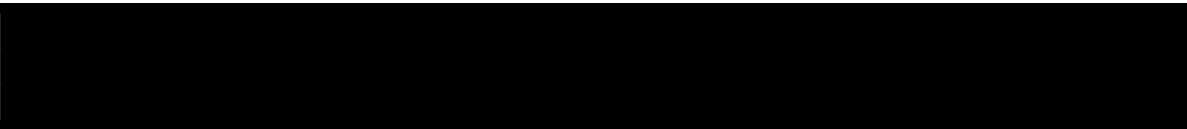

We will be converting bedgraph files to bigWig later. For that conversion, we need a file containing chromosome name and its size. We already know that the chromosome name

is the first column, and looking at the description of samtools faidx above, we see that the length is stored in the second column.

### Task

1. Using **grep** and **cut**, extract all chromosome names and their length.
2. Store the names in the `$dir_atac/ref_genome` folder in a file named `Ssal_chrm_sizes.txt` [instant]

### Solution

## 4 Peak Calling

The tool we are using for peak calling is Genrich. Genrich was developed by John Gaspar, previous of Harvard FAS Informatics. The default method is for ChIP-seq peak-calling, but there is an ATAC-seq specific mode. To account for the manner in which the Tn5 enzyme inserts itself into the genome, Genrich centers a 100 bp interval at each end of each fragment. It uses the log-normal distribution to calculate p-values for each base of the genome.

Some advantages over MACS include how much faster it runs (it is written in C), as well as the capability of calling peaks for multiple replicates collectively. Unfortunately, Genrich is yet to be published.

### 4.1 Sort by read names

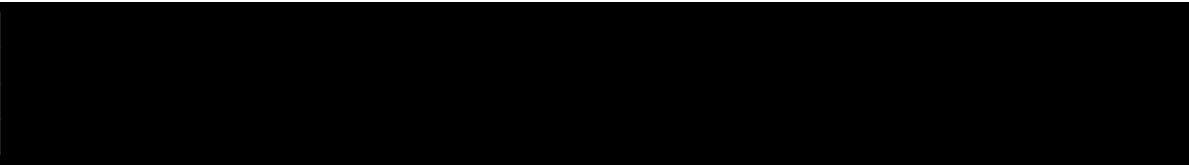

Genrich requires that the BAM files are sorted by read names, not by mapping position, which they currently are.

Sort bam file by reads, name it *B-1.sortedByRead.bam* and store it in *results/genrich/*. Samtools documentation: <http://www.htslib.org/doc/samtools.html>

### Task

1. Using the **juettemann/samtools:latest** container **sort** `$dir_atac/data/B-1.bam` by read names  
(Documentation <http://www.htslib.org/doc/samtools-sort.html>)
2. Name the output file **B-1.sortedByRead.bam** and store it in the folder **\$dir\_atac/results/genrich/**
3. Set number of sorting and compression threads to 8
4. Runtime: 4m48s

### Solution

## 4.2 Peak calling

Next step is the peak calling with Genrich.

### Task

1. Pull the container **juettemann/genrich:0.6**  
(Documentation <https://github.com/jsh58/Genrich>)
2. Using **\$dir\_atac/results/genrich/B-1.sortedByRead.bam** as input, create:
  - ENCODE narrowPeak format
  - bedgraph-ish file for pileups and p-values
  - Set:
    - Maximum q-value = 0.05
    - print status to stderr
    - ATAC-seq mode
  - Redirect the STDERR output to **\$dir\_atac/logs/genrich\_B-1.log**
  - Runtime: 7m19s

## Solution

## 5 Quality Control

We will be using two tools for investigating the results of the peak calling, Integrated Genome Browser (IGV) and `ataqv`.

### 5.1 IGV

A common way to get an idea about the quality of the results is looking at the data in a genome browser. As most publicly available web based browsers have a limit on the size of the file that you can upload, we will be using IGV. Visualising the read density along the chromosomes (bigwig files) and the peaks defined by Genrich(narrowPeak file).

#### 5.1.1 Convert bedGraph to BigWig

The bigWig format is for display of dense, continuous data that will be displayed as a graph. The main advantage of the bigWig files is that only the portions of the files needed to display a particular region are transferred, so for large data sets bigWig is considerably faster than any non-indexed formats.

#### Create compliant bedGraph

The .bedGraph-ish out from Genrich can easily be converted to bigWig. To create a compliant bedGraph file, extra columns and headers must be removed.

#### Task

1. Using **grep** and **cut**, extract all chromosome names and columns 1-4
2. Store the names in the `$dir_atac/results/genrich/` folder in a file named **B-1.k.fixed.bedGraph**
3. Runtime: Instant

### Solution

#### Create bigWig

UCSC provides a tool to convert bedGraph to bigWig (part of the Kent tools). It takes 3 arguments:

**bedGraphToBigWig** *<in.bedGraph>* *<chrom.sizes>* *<outBigWig.bw>*

### Task

1. Using [quay.io/biocontainers/ucsc-bedgraphtobigwig:377-h0b8a92\\_2](https://quay.io/biocontainers/ucsc-bedgraphtobigwig:377-h0b8a92_2), convert **B-1.k.fixed.bedGraph** to **B-1.bw**
2. Save the file in `$dir_atac/results/genrich/`
3. Runtime: 1m18s

### Solution

#### 5.1.2 Launch IGV

The IGV browser is launched from the command line.

### Task

1. Open a new terminal and run
2. `igv`

## ATAC-seq tutorial

### 5.1.3 Load Genome and Tracks

IGV loads its genomes from the Broad Institute, and these genomes use RefSeq accessions as chromosome names. Refseq accessions are different from the ones used by the submitter of the genome (which Ensembl uses), therefore we need to load this standard genome manually.

#### Task

1. In the IGV window, click *Genomes* -> *Load Genome from File* -> navigate to *train-aquaafaang-bioinf/atac-seq/ref\_genome/* and select  
-> **Salmo\_salar.ICSASG\_v2.dna.toplevel.fa**
2. In the IGV window, click *File* -> *Load from File* -> navigate to *train-aquaafaang-bioinf/atac-seq/results/genrich/* and select  
-> *Salmo\_salar.ICSASG\_v2.103.chr.sorted.gtf* -> *B-1.bw*  
-> *B-1.narrowPeak*  
-> *L-1.bw*  
-> *L-1.narrowPeak*

If you want to go further and get an idea about the differences between the replicates, simply load all other \*.bw and \*.narrowPeak files the same way.

### 5.1.4 Explore using IGV

We will investigate two genes, *Neurogenic differentiation factor* (**NDF1**) which is involved in neuron development, and *Hepatocyte nuclear factor 1-alpha* (**hnf1a**) which is involved in liver development.

#### NDF1

The genomic coordinates of NDF1 are *ssa25:27,019,821-27,030,126*. Copy and paste them in the search box and click Go. Figure 1 shows the expected result. The sample B-1 has open chromatin upstream of the NDF1 gene (peak\_59291), whereby the liver samples show closed chromatin.

## ATAC-seq tutorial

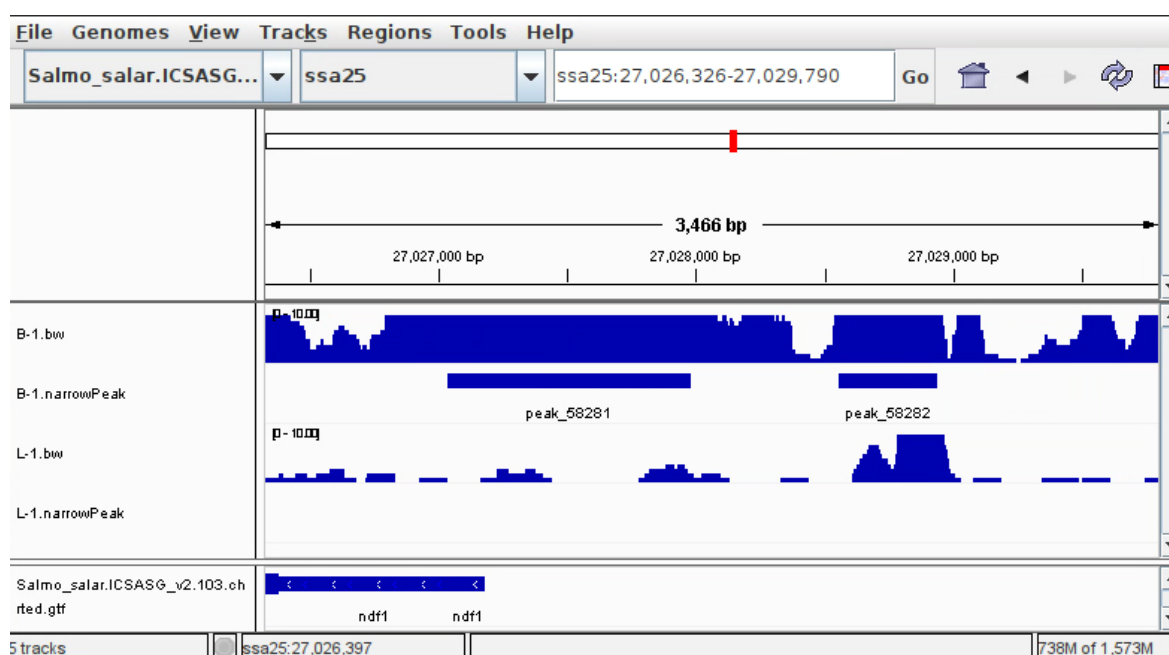

Figure 1: IGV showing area around the NDF1 gene

### hnf1a

The genomic coordinates of *hnf1a* are *ssa20:19,522,855-19,530,228*. Copy and paste them in the search box and click Go. In figure 2, the roles are reversed - the liver sample shows open chromatin upstream of the *hnf1a* gene (peak\_51067).

## ATAC-seq tutorial

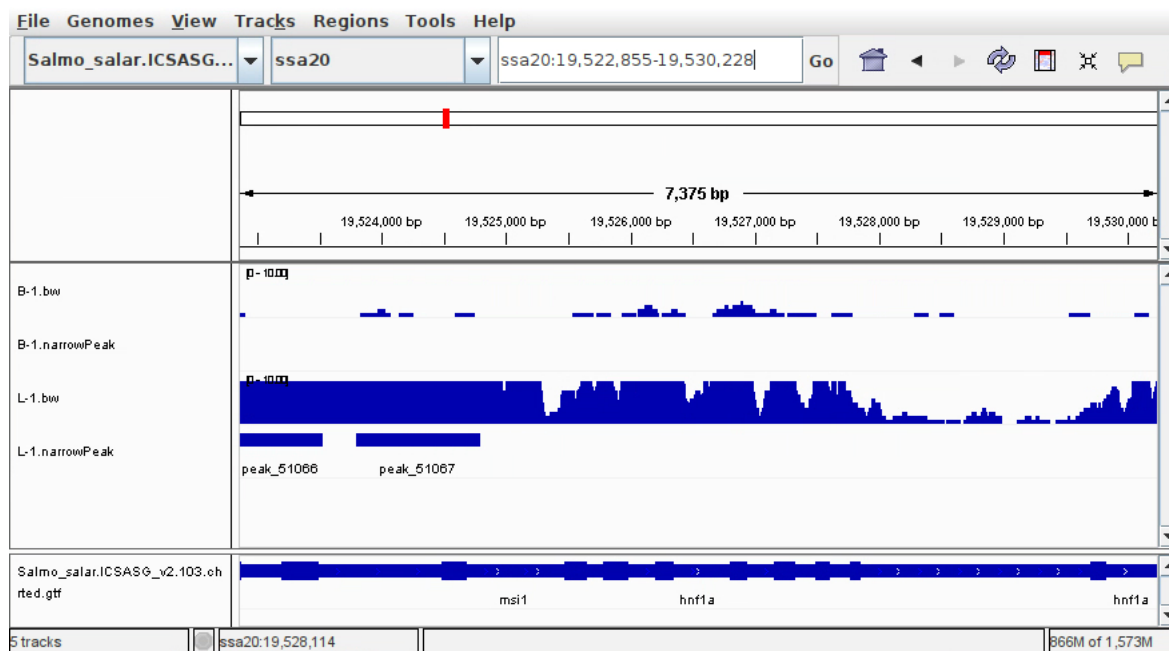

Figure 2: IGV showing area around the *hnf1a* gene

The overlap between the *msi1* gene and *hnf1a* can easily be explained by having a look at the Ensembl genome browser (figure 3), the last intron of transcript 202 extends into *hnf1*.

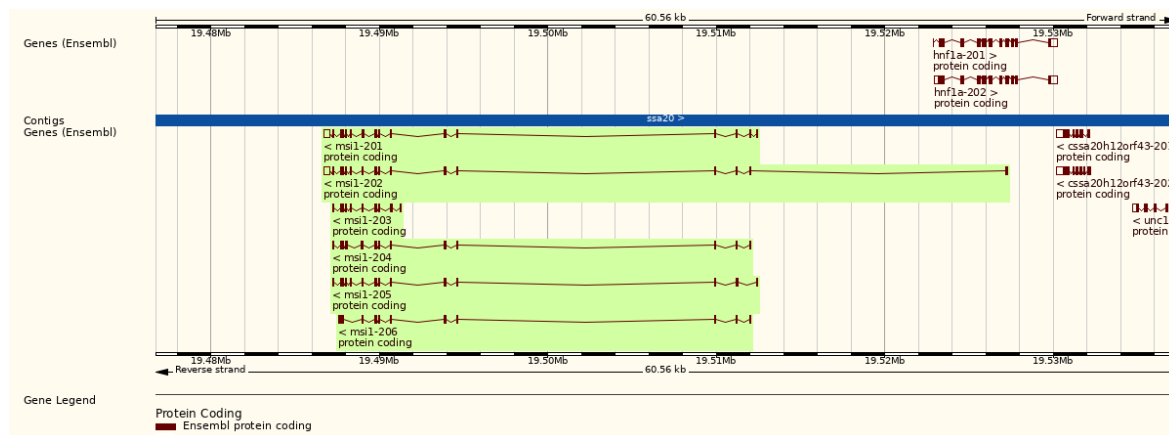

Figure 3: *msi1* gene in the Ensembl genome browser

## 5.2 ATAQV

Ataqv is a toolkit for measuring and comparing a broad range of ATAC-seq quality metrics. It makes it easier to spot differences that might be caused by library prep or sequencing. We will investigate two features: high quality autosomal alignment (HQAA) fragment length distribution (FLD) and transcription start sites (TSS) enrichment.

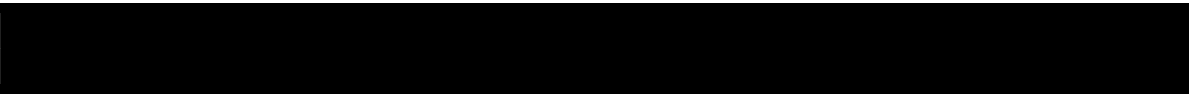

### 5.2.1 Index BAM

To run ATACV the BAM file needs to be indexed. Using samtools, index B-1.bam.

#### Task

1. Using **juettemann/samtools** index, convert **\$dir\_atac/data/B-1.bam** to **B-1.bw**
2. Name the output **B-1.bam.bai** and save the file in **\$dir\_atac/data**
3. Runtime: 1m12

#### Solution

### 5.2.2 Run ATACV

The main program, ataqv, examines our aligned reads and reports some basic metrics.

#### Task

1. Using **quay.io/biocontainers/ataqv:1.2.1-py27h97b49fa\_1** ataqv run ataqv  
(Documentation: <https://github.com/ParkerLab/ataqv>)
2. ataqv needs information about our terminal, pass **-e TERM=xterm** to the container.
3. Input
  - organism name is Ssal
  - alignment file \$dir\_atac/data/B-1.bam
  - peak file is \$dir\_atac/results/genrich/B-1.narrowPeak
  - TSS file is \$dir\_atac//ref\_genome/SsalTSS\_NCBI.bed
  - autosomal reference is \$dir\_atac//ref\_genome/Ssal\_chrm.txt
4. Output
  - metrics file \$dir\_atac/results/ataqv/B-1.ataqv.json
5. Runtime 6m21

### Solution

#### 5.2.3 Visualising results

The mkarv script that collects ataqv results and sets up a web application to visualize them.

### Task

1. Using `quay.io/biocontainers/ataqv:1.2.1-py27h97b49fa_1 ataqv run mkarv`  
(Documentation: <https://github.com/ParkerLab/ataqv>)
2. Pass **-e TERM=xterm** to the container.
3. Input
  - results/mkarv/ataqv\_good\_html
  - whitespace separated list of all 8 B & L \*.ataqv.json files, e.g. **results/ataqv/B-1.ataqv.json**

### Solution

Now we do the same for the spleen samples.

## Task

1. Using `quay.io/biocontainers/ataqv:1.2.1-py27h97b49fa_1 ataqv run mkarv`  
(Documentation: <https://github.com/ParkerLab/ataqv>)
2. Pass `-e TERM=xterm` to the container.
3. Input
  - `results/mkarv/ataqv_bad_html`
  - whitespace separated list of all 4 SP \*.ataqv.json files, e.g. `results/ataqv/SP-1.ataqv.json`
4. Runtime: 10s

## Solution

In your webbrowser, navigate to directory `$dir_atac/results/markv/ataqv_good_html` and open the index.html. Explore the different graphs and also the table tab.

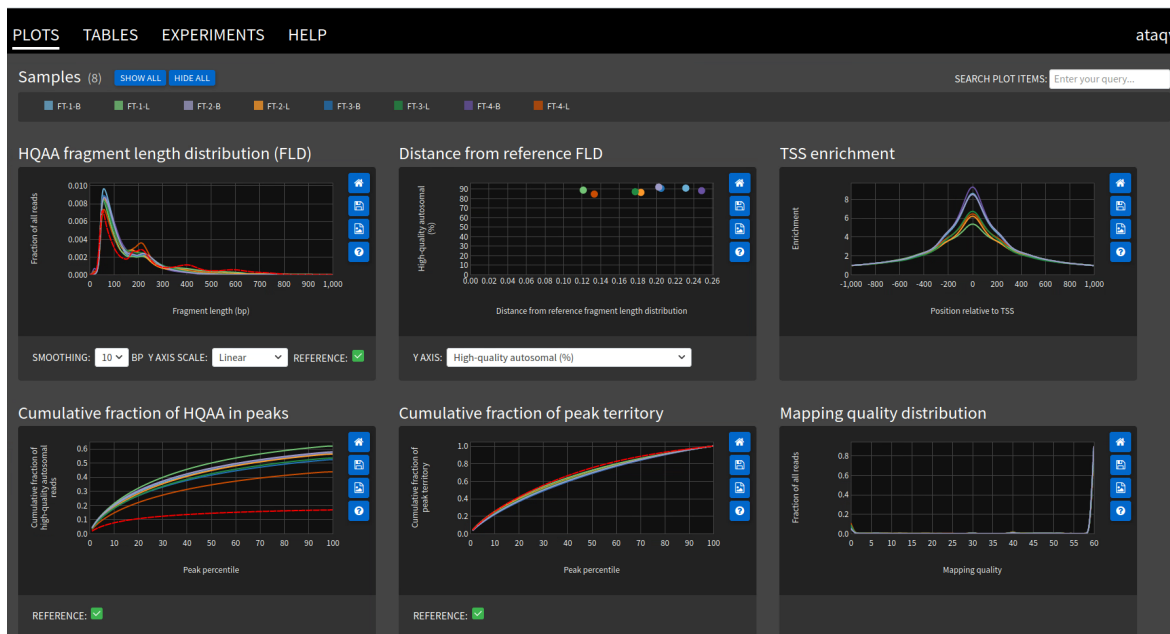

Figure 4: Result of a successful ATAC-seq experiment visualised using ataqv

## ATAC-seq tutorial

Now do the same for spleen sample results (\$dir\_atac/results/markv/ataqv\_good\_html/index.html). What differences do you see?

Figure 5: Result of an unsuccessful ATAC-seq experiment visualised using ataqv
